

What concerns can be treated and what kind of results can be expected?

- Red Veins and Spider Naevi

Fading begins about three weeks after treatment, with the broken capillaries beginning to disappear. Typically, up to three treatments may be required, although there may be a noticeable difference after just one treatment.

- Skin Tags

These small blemishes are cauterised and removed instantly, with small red marks or scabbing appearing after treatment. These will disappear after 7-10 days.

- Milia

The current cauterises the blemish and the milia is reabsorbed back into the skin. Results can start to show up to a month after treatment.

- Warts/Verrucas

Often two treatments are needed, taken eight weeks apart, to remove warts and verrucas.

- Seborrhoeic Keratosis

The current is used to lift away and cauterise, and scabs will appear for up to two weeks. Once these have healed, you will see that the blemish has been fully removed.

- Syringoma

The current applied will shrink the blemish. Small crusts and swellings will then appear, taking up to two weeks to heal. Several treatments may be needed, depending on the area to be treated.

- Xanthelasma

The current shrinks the blemish, small crusts and swellings will appear which will take up to 2 weeks to heal. Several treatments may be needed depending on the area to be treated.

- Age Spot Removal

These blemishes are lifted away and cauterised, leaving small scabs that will disappear over a couple of weeks.

- Dermatosa Papulosa Nigra

Dermatosa Papulosa Nigra are small brown or black raised areas of skin that affect one third of people with Fitzpatrick skin types 5 and 6. In many cases, Dermatosa Papulosa Nigra is a genetic condition that appears on the face, upper cheeks and temples, eyes and chest and increases with age. While Dermatosa Papulosa Nigra does not pose a threat to your health, it can have an impact on your self-confidence and mental wellbeing.

- Blood Spots

Cherry Angioma are small blood spots that are benign vascular blemishes. They can vary in size from small pin dots to as large as a penny; and in colour from bright red to darker tones. Cherry angioma are not painful, but may bleed when scratched and can become distressing, particularly if they are in difficult to mask areas.
